- Scheme of the talk

Basic overview

- The determinant of a Matrix A can be determinate by using:

- The characteristic polynomial and the elementary symmetric functions:

Main Result

An application: The elementary symmetric functions

1. The Laplace expansion:

$$\det(A) = \sum_{j=1}^n (-1)^{i+j} a_{i,j} \det(A_{i,j}) = \sum_{i=1}^n (-1)^{i+j} a_{i,j} \det(A_{i,j}).$$

2. The alternating sum:

$$\det(A) = \sum_{\sigma \in P_n} \operatorname{sgn}(\sigma) a_{1,\sigma(1)} a_{2,\sigma(2)} \cdots a_{n,\sigma(n)},$$

The characteristic polynomial and the elementary symmetric functions:

- Scheme of the talk

Basic overview

- The determinant of a Matrix A can be determinate by using:
 - The characteristic polynomial and the elementary symmetric functions:

Main Result

An application: The elementary symmetric functions

1. Definition:

$$\chi_A(\lambda) \stackrel{\text{def}}{=} \det(\lambda I_n - A) = \prod_{j=1}^n (\lambda - \lambda_j).$$

2. The Elementary symmetric functions: For $k = 1, 2, \dots, n$,

$$S_k \equiv S_k(\lambda_1, \dots, \lambda_n) \stackrel{\text{def}}{=} \sum_{1 \leq i_1 \leq i_2 \leq \dots \leq i_k} \lambda_{i_1} \lambda_{i_2} \cdots \lambda_{i_k}$$

3. The Newton-Girard formulas: For any $m \in \mathbb{N}$,

$$m S_m = \sum_{j=1}^m (-1)^j S_j T_{m-j},$$

where $T_j(\lambda_1, \dots, \lambda_n) \stackrel{\text{def}}{=} S_1(\lambda_1^j, \dots, \lambda_n^j)$.

An application: The elementary symmetric functions

Theorem: Given $A \in M_n$ and an integer N , with $N \geq n + 1$. For any N -tuple $S = (A_1, A_2, \dots, A_N)$, $A_i \in M_n$, $i = 1, \dots, N$, the following relation holds:

$$\sum_{k=0}^N (-1)^k \sum_{\substack{\Omega \in \Sigma(S) \\ |\Omega|=k}} \det(A + \sum_{A_i \in \Omega} A_i) = 0,$$

understanding that $|\Omega| = k$ means that Ω is a formal sum with k summands, and that $A_i \in \Omega$ means that A_i is a summand in Ω .

$$\begin{aligned} \det(A_1 + A_2 + A_3 + A_4) &= \det(A_1 + A_2 + A_3) + \det(A_1 + A_2 + A_4) \\ &\quad + \det(A_1 + A_3 + A_4) + \det(A_2 + A_3 + A_4) \\ &\quad - \det(A_1 + A_2) - \det(A_1 + A_3) - \det(A_1 + A_4) \\ &\quad - \det(A_2 + A_3) - \det(A_2 + A_4) - \det(A_3 + A_4) \\ &\quad + \det(A_1) + \det(A_2) + \det(A_3) + \det(A_4). \end{aligned}$$

- A remark about the Theorem

An application: The elementary symmetric functions

Corollary 1: Under the conditions of the Theorem. For any index sets $\alpha, \beta \subseteq \{1, 2, \dots, n\}$ of size τ , $N \geq \tau + 1$,

$$\sum_{k=0}^N (-1)^k \sum_{\substack{\Omega \in \Sigma(S) \\ |\Omega|=k}} \det(A(\alpha, \beta) + \sum_{A_i \in \Omega} A_i(\alpha, \beta)) = 0.$$

Definition: The k -th elementary symmetric function is defined as:

$$S_k(A) \stackrel{\text{def}}{=} \sum_{|\alpha|=k} \det(A(\alpha, \alpha)).$$

Corollary 2: For any non-negative τ , N , $N \geq \tau + 1$,

$$\sum_{k=0}^N (-1)^k \sum_{\substack{\Omega \in \Sigma(S) \\ |\Omega|=k}} S_\tau(A + \sum_{A_i \in \Omega} A_i) = 0.$$

A remark about the Theorem

- Scheme of the talk

Basic overview

Main Result

- Main Result:
- The elementary symmetric functions:
- **A remark about the Theorem**

An application: The elementary symmetric functions

The Theorem is optimal with respect to the range of N , i.e. for any positive integer n , it is possible to find n -tuples of M_n so that the equality given in Theorem is not true.

For instance, taking

$$A_i = \text{diag}(e_i), \quad i = 1, 2, \dots, n, \quad A = xe_1, \quad x \in \mathbb{R},$$

where $\{e_1, e_2, \dots, e_n\}$ is the canonical basis of \mathbb{R}^n , it is straightforward to check that

$$\sum_{k=0}^n (-1)^k \sum_{\substack{\Omega \in \Sigma(S) \\ |\Omega|=k}} \det(A + \sum_{A_i \in \Omega} A_i) = (-1)^n (1 + x - x) \neq 0.$$

Main Result

An application: The elementary symmetric functions

- **Some computation:**
- More identities
- Two conjectures on elementary symmetric functions and positive definite matrices
- Finally

$$S_2(A_1 + A_2) = S_2(A_1) + S_2(A_2) + S_1(A_1)S_1(A_2) - S_1(A_1A_2),$$

$$\begin{aligned} S_3(A_1 + A_2) = & S_3(A_1) + S_3(A_2) - S_1(A_1 + A_2)S_1(A_1A_2) \\ & + S_1(A_1)S_2(A_2) + S_1(A_2)S_2(A_1) \\ & + S_1(A_1^2A_2) + S_1(A_1A_2^2). \end{aligned}$$

Question: Can we, in general, express S_k of a set of j n -by- n matrices, $j \leq k$, in an analogous way?.

Answer: YES.

More identities

- Scheme of the talk

Basic overview

Main Result

An application: The elementary symmetric functions

- Some computation:
- **More identities**
- Two conjectures on elementary symmetric functions and positive definite matrices
- Finally

$$S_k(A_1 + A_2 + \cdots + A_{k+l}) = \sum_{j=0}^k (-1)^j \binom{j+l-1}{l-1} \sum_{|\Omega|=k-j} S_k \left(\sum_{A_i \in \Omega} A_i \right).$$

$$S_1(A^m) = \det \begin{pmatrix} S_1(A) & 1 & 0 & \cdots & 0 \\ 2S_2(A) & S_1(A) & 1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ mS_m(A) & S_{m-1}(A) & S_{m-2}(A) & \cdots & S_1(A) \end{pmatrix}.$$

Two conjectures on elementary symmetric functions and positive definite matrices

Basic overview

Main Result

An application: The elementary symmetric functions

- Some computation:
- More identities
- **Two conjectures on elementary symmetric functions and positive definite matrices**
- Finally

The Bessis-Moussa-Villani conjecture: *The polynomial $p(t) := \text{Tr}((A + tB)^m) \in \mathbb{R}[t]$, has only nonnegative coefficients whenever $A, B \in M_r$ are positive semidefinite matrices.*

In fact, some numerical evidences and the Newton-Girard formulas suggested to us to consider a more general conjecture.

Positivity Conjecture :

The polynomial $S_k((A + tB)^l) \in \mathbb{R}[t]$, has only nonnegative coefficients whenever $A, B \in M_r$ are positive semidefinite matrices for every $k = 0, 1, \dots, r$.
